Abstract The Sun and its solar wind are currently exhibiting extremely low densities and magnetic field strengths, representing states that have never been observed during the space age. The highly abnormal solar activity between cycles 23 and 24 has caused the longest solar minimum in over 80 years and continues into the unusually small solar maximum of cycle 24. As a result of the remarkably weak solar activity, we have also observed the highest fluxes of galactic cosmic rays in the space age and relatively small solar energetic particle events. We use observations from the Cosmic Ray Telescope for the Effects of Radiation (CRaTER) on the Lunar Reconnaissance Orbiter to examine the implications of these highly unusual solar conditions for human space exploration. We show that while these conditions are not a show stopper for long-duration missions (e.g., to the Moon, an asteroid, or Mars), galactic cosmic ray radiation remains a significant and worsening factor that limits mission durations. While solar energetic particle events in cycle 24 present some hazard, the accumulated doses for astronauts behind 10 g/cm² shielding are well below current dose limits. Galactic cosmic radiation presents a more significant challenge: the time
Protracted Min (23) and Mini Max (24)

Continued Decay of Magnetic Flux in the Dalton-like Minimum

CRaTER Concept of Operations
Quick CRaTER Overview

- Measures > 12 MeV/nuc particles
- 6 detectors (D1-D6) with Tissue Equivalent Plastic (TEP) between pairs of detectors
  - Thick and thin detectors with different gains allow a large range of Linear Energy Transfer (LET) to be sampled
  - TEP mimics absorption of energy by human tissue as radiation passed through telescope
- Senses particles from zenith and nadir directions
- Any energy deposit in any detector triggers an ‘event’, in which all energy deposits from all detectors are recorded
- Data products are in terms of LET, the amount of energy deposited per path-length ($\Delta E/\Delta x$) as a particle transits through detector
Slab Turbulence Model for Modulation of Galactic Cosmic Rays

- Modulation Potential characterizes evolution of GCRs fluxes (protons & heavy ions)

\[ \Phi = |Ze|\phi(r) \]

\[ \phi(r) = \int_{r}^{R_b} dx \frac{V(x)}{3\kappa_1(x)} \]

\[ \kappa_\parallel \propto \frac{r_g^2}{F^2} \quad F = \frac{\delta B}{B} \]

\[ \Phi \propto B^2 \]

\[ \Phi \propto |B|^{\gamma} \]

\[ \gamma = 1.87 \]

\[ y = -1.0811 + 1.8766x \quad R = 0.91431 \]

2006-2013
- Feb-Aug, 2013
Details about the Modeling

• GCR fluxes modeled using slab-turbulence + force-free model
  – Similar model as Badhwar O’Neill, however modulation potential scaled differently based on observations

• Utilize a three-layer version of HZETRN 2005 and HZETRN 2010 for modeling doses, dose-equivalents, and effective dose
• Longer-term trend deduced from observed Heliospheric Magnetic field
• Continues trend observed by ACE and CRaTER

Approach, Assumptions

• Direct observations critical for validating models!!!
• GCR fluxes modeled using slab-turbulence + force-free model
  – Modulation potential scaled with observed magnetic field strength
  – Dose-rate validated with ACE and CRaTER
• Three-layer version of HZETRN 2005 and HZETRN 2010 for modeling doses, dose-equivalents, and effective dose
  – LET spectra from HZETRN validated with CRaTER
Implications of the Worsening GCR Radiation Environment

• Direct observations (e.g., from LRO/CRaTER and MSL/Rad) critical!
• Deepest Solar Minimum and Weakest Maximum more than 80 years
  – Increased GCR radiation intensity, particularly in solar minima
  – Reduced allowable time in deep space for astronauts
  – Lower probability of SEP events
• Need Improved Understanding/Predictability of SEPs
  – Probability of Extreme Events
  – Resolve physics and predictability of extreme events
Power of Distributed Observers: Broad Longitudinal extent of SEP events has proved very useful for predicting SEP spectra and radiation doses at different locations in the inner heliosphere. Figures below show two recent papers by which SEP time profiles, onset, and radiation estimates were successfully predicted at Mars (Odyssey) and Ulysses located at 1.44 AU and 4.91 AU, respectively. 1 AU measurement from ACE, SoHO, and GOES.
SEP events with PREDICCS

SEP Events During 2012: Indicators of Larger SEP Events in the New Cycle (24)

• Shown here are the major SEP events of 2012 and the comparisons between CRaTER observations (blue) and prediccs predictions (red and green).

• Agreement reveals overall accuracy of models, while deviations likely reveal heavy ion contributions to dose observed by CRaTER.
<Q> = 3.8 (thick shield, 16 g/cm²)

<Q> = 5.8 (thin shield, 0.3 g/cm²)
